

× × × × When a photon does encounter an atomic particle, it transfers energy to the particle. The energy may be reemitted back the way it came (reflected), scattered in a different direction or transmitted forward into the material.

The energy of photons used for optical spectroscopic measurements of various quanta

EHz : exahertz ( $10^{18}$ ) - ZHz : zettahertz ( $10^{21}$ ) - YHz : yottahertz ( $10^{24}$ )

The energy of photons used for optical spectroscopic measurements of various quanta

Instrumentations using radiation for material analysis need to be optimized :

- source characteristics
- detection characteristics
- sample environment
- mechanical design

| We can propose instrume  | ents for this expertise:                                  |
|--------------------------|---|
| - X-ray diffraction : pł | nase analysis, identification and quantification of phase |
| - X-ray diffusion (SAXS) | : nanoparticles morphology                                |
| - X-ray fluorescence     | : elemental analysis                                      |
| - X-ray imaging          | : image of X-ray absorption                               |
| - X-ray reflection       | : nanometric coating analysis                             |

# **Focus on X-ray diffraction**

## Which material is able to diffract?

Anything which has a structure at the nanometric scale, with enough contrast.

**Structure** : ordering at the atomic scale Then, mostly crystallized material in bulk or powder but even in liquid cristals or in smoke

**Contrast** : X-ray interacts with electronic level Then, heavy atoms => high contrast

Each tool or instrument is designed to fulfill a task

According to its characteristics, it will be used in a defined range ...

A tool or an instrument can be designed according to the definition of a need ...  $\wedge$ 

Instrument

× × ×

A hammer is designed according to the type of nail, and for the destination

### => Same type of instrument can have different design depending on the application

Instrument is designed for the need we are looking for. It allows to measure and quantify physical parameters (length, weight, power, energy, time...)

# **X-ray diffraction instrument**

# **X-ray diffraction instrument**

A light emission characterized by :

- a spectral range
- a solid angle
- intensity
- dimension and shape of the source

Optimizing the characteristics of a source allows to focus on a given interaction

Molybdenum spectrum vs the applied voltage

| s is achieved by | v using appropr   | iate optics (1D, 2D, r          | monochromator m                  | irror collimator  | elite )                   |

This is achieved by using appropriate optics (1D, 2D, monochromator, mirror, collimator, slits ...)

# **X-ray diffraction instrument**

![](_page_10_Picture_1.jpeg)

**Dx** : Diffraction plane

**F** : focus of the source

**M:** Optical position (monochromator, mirror), involving a primary beam deviation

**G** : Goniometer center where is localized the sample

 $\boldsymbol{\mathsf{S}}$  : Sample position

**D**: Diffraction device

**Dir X:** Direction of the primary beam

**Dir Y:** Direction perpendicular to the diffraction plane (axial direction)

**Dir Z:** Direction perpendicular to the sample surface (equatorial direction)

### Sample orientation is defined by 3 Euleriean angles:

The Goniometer

- " $\Omega^{\prime\prime}$  angle is the incident angle on the sample surface

- "  $\boldsymbol{\phi}$  " angle is the rotation belongs the normal axis to the sample surface

- " $\chi$ " angle allows to tilt sample belongs the axis intercept of the diffraction plane and sample surface

### Remark:

- "20" angle belongs to the detection part

# X-Ray diffraction, powder vs crystal

der

### **Powder sample :**

- Large number of grains probed by X-rays
- Grains are small according to beam size (20μm) -**N**O
- Each grain is able to diffract according to its orientation
- => several diffracted beam for a fixed sample orientation
- Diffraction plane intercepts all diffraction cones

![](_page_12_Figure_7.jpeg)

### **Oriented polycrystal :**

 large number of crystallite having a rule for organization

> exture diffractometer setup

### Single cristal :

setup

- 1 unique grain probed by X-rays
- 1 unique diffacted signal for a given orientation of cristal
- => only possibilities to record several diffracted beam
- Moving cristal by using a goniometer and
- monochromatic beam
- Not moving cristal, but using a polychromatic beam
- $\rightarrow$  Laue method (consult us to define the instrument)

![](_page_12_Figure_19.jpeg)

# **X-Ray diffraction, detection types**

### **OD Detection :**

Acquisition is done Stepwise

2θ and statistics are time dependent

![](_page_13_Figure_4.jpeg)

### **1D Detection :**

Acquisition is done in snapshots Statistics is time dependent

### **2D Detection :**

Acquisition is done in snapshots

Statistics is time dependent

Texture information but point beam required

# **Function matter**

![](_page_14_Figure_1.jpeg)

Phases

whatever the state, XRD allows to evidence and measure structural parameters in matter

# **Instrumental function for XRD**

### Instrumental function is governed by all components of the XRD instrument :

- -- source characteristics
- -- optics and collimation
- -- detection device
- -- sample environment

### XRD components should be compatible to each other

Example : 1D optic is not recommended with a 2D detector (equatorial aberration)

### -**The good knowledge of the instrumental function allows to estimate as well the quality of the result** -Example : absorption correction or LP correction are not the same in Bragg Brentano or in Debye Scherrer

### The instrument must be adapted to the requested measurement

-Example : performing transmission measurement with Bragg-Brentano XRD is not appropriate

### - Instrumental conditions must be correctly chosen (reproducibility of results)

-Example : choose of the appropriate wavelength vs sample

### - Use of appropriate standards

Example : in reflection, eccentricity is influenced by transparency. Using standard with same absorption can correct this

# **Instrumental function for XRD**

### **Elastic coherent interaction :**

**reflectometrie** : investigation on thin film for measuring thickness, roughness and density **diffraction** : investigation on phases **absorption** : imaging and radiography.

### **Incoherent elastic interaction :**

diffusion by a rough surface or cristalline defects.

Angle-energy map measured for a BaSO4 rich sample using Mo radiation not monochromatised and scanning the SDD detector from 5 to 47. in 2θ.

### Ref. L. Lutterotti, U. Trento

### **Expected characteristics**:

- 50mm Strip detector, composed by 100microns (could be 50?) linear pixel width

- High dynamic per pixel

- Each pixel is able to measure EDX with a resolution better then 180eV

- Light weight and low consumption
- No gas needed
- Real time detector with low dead time

- Possibility to combine several detectors in order to cover a larger intercept of the Debye cones

- Efficiency for energy range from 1keV to 30keV

# XRD for single crystal with monochromatic beam – parallel beam geometry

Parallel beam geometry With flat cristals (1, 2 or 4 bounds)

![](_page_26_Figure_2.jpeg)

Sample hold by appropriate goniometer Different type of configuration

# XRD for single crystal with polychromatic beam – parallel beam geometry

The Laue method is mainly used to determine the orientation of large single crystals. White radiation is reflected from, or transmitted through, a fixed crystal.

The diffracted beams form arrays of spots, that lie on curves on the film. The Bragg angle is fixed for every set of planes in the crystal. Each set of planes picks out and diffracts the particular wavelength from the white radiation that satisfies the Bragg law for the values of d and  $\theta$  involved.

### **Experimental**

There are two practical variants of the Laue method, the back-reflection and the transmission Laue method:

### **Back-reflection Laue**

In the back-reflection method, the film is placed **between** the x-ray source and the crystal. The beams which are diffracted in a backward direction are recorded. One side of the cone of Laue reflections is defined by the transmitted beam. The film intersects the cone, with the diffraction spots generally lying on an hyperbola.

![](_page_27_Picture_7.jpeg)

### **Transmission Laue**

In the transmission Laue method, the film is placed **behind** the crystal to record beams which are transmitted through the crystal. One side of the cone of Laue reflections is defined by the transmitted beam. The film intersects the cone, with the diffraction spots generally lying on an ellipse.
